## ABSTRACT

**Objective** To examine recent changes in sex-specific and age-specific suicide mortality by method across countries.

**Methods** Using mortality data from the WHO mortality database, we compared sex-specific, age-specific and country-specific suicide mortality by method between 2000 and 2015. We considered seven major suicide methods: poisoning by pesticides, all other poisoning, firearms and explosives, hanging, jumping from height, drowning and other methods. Changes in suicide mortality were quantified using negative binomial models among three age groups (15–44 years, 45–64 years, and 65 years and above) for males and females separately.

**Results** Suicide mortality declined substantially for both sexes and all three age groups studied in 37 of the 58 included countries between 2000 and 2015. Males consistently had much higher suicide mortality rates than females in all 58 countries. Hanging was the most common suicide method in the majority of 58 countries. Sex-specific suicide mortality varied across 58 countries significantly for all three age groups. The spectrum of suicide method generally remained stable for 28 of 58 included countries; notable changes occurred in the other 30 countries, including especially Colombia, Finland and Trinidad and Tobago.

**Conclusion** Likely as a result of prevention efforts as well as sociodemographic changes, suicide mortality decreased substantially in 37 of the included 58 countries between 2000 and 2015. Further actions are needed to explore specific drivers of the recent changes (particularly for increases in eight countries), to understand substantial disparities in suicide rates across countries, and to develop interventions to reduce suicide rates globally.

## INTRODUCTION

Suicide is a significant public health problem internationally and is responsible for over 793 800 deaths in 2017 according to estimates from the Global Burden of Disease (GBD) study group.<sup>1</sup> Although suicide mortality varies substantially by sex and age group and across regions and countries,<sup>2</sup> suicide places among the top three causes of death for people aged 15–44 years in several countries.<sup>1</sup> The United Nations lists suicide prevention as a specific target in the Sustainable Development Goals (SDGs), ‘reducing by one-third premature mortality from non-communicable diseases by 2030 (including suicide)’.<sup>3</sup>

In the past few decades, successful suicide prevention measures have been developed in many countries to reduce self-harm and suicide. Implemented strategies include improved access to mental health and welfare services, reduced use of alcohol and promotion of responsible media reporting about suicide.<sup>2</sup> Perhaps the most successful suicide prevention strategy, however, is restricting access to lethal means.<sup>2,4,5</sup> This prevention strategy has been widely promoted to prevent suicide by international organisations such as WHO and the UNICEF, individual governments, non-government organisations, as well as injury researchers in the last decade.<sup>6–9</sup>

In order to best promote efforts to prevent suicide, including by restricting access to lethal means, it is important to understand the patterns of sex-specific and age-specific suicide mortality by method across individual countries around the world. Previous research offers some indication of these patterns. One publication, for example, reported varying spectrums of suicide methods and method-specific suicide mortality across sex, age groups, and regions and countries before 2005,<sup>10</sup> revealing hanging as the predominant method of suicide in most countries and firearms suicide in the USA. In addition, a few studies report suicide mortality patterns for specific suicide methods among certain age groups in a single nation or region.<sup>11–15</sup> As an example, one study reported that firearm suicide mortality decreased globally from 1990 to 2016.<sup>11</sup> Another study on suicide by charcoal burning showed that charcoal-burning suicide mortality increased significantly in some East/Southeast Asian countries/territories in the first decade of the 21st century.<sup>12</sup> No published study examines, however, recent changes within countries across the world in sex-specific and age-specific suicide mortality by method. Since epidemiological characteristics may change as the result of prevention efforts and socioeconomic development, this knowledge would be valuable for prevention planning by a range of stakeholders.

The WHO mortality database is a freely available data source with national-level mortality data reported by all WHO Member States from 1979 to 2016.<sup>16</sup> The database provides detailed data on the methods used in suicide, extending beyond the two cause/method groups (self-harm by firearm and self-harm by other specified means) used in the GBD database.<sup>1</sup>

Using the latest WHO mortality data, therefore, we compared sex-specific and age-specific suicide

mortality by method between 2000 and 2015 in all member countries covered by the WHO mortality database.

## METHODS

### Data source

Suicide mortality data were extracted from the WHO mortality database, which provides detailed death registration data for about 150 countries and regions.<sup>16</sup> To ensure we obtained the most statistically reliable data possible concerning sex-specific, age-specific and method-specific suicide mortality rates, we applied the following criteria to determine eligible countries for this study: (1) country/territory's vital registration data were assessed as medium or high quality by WHO<sup>17</sup>; (2) at least 8 years of data were available between 2000 and 2015 in the WHO mortality database; (3) at least 100 suicide deaths were reported for people aged 15 years and older in a single year and (4) deaths were coded using the 10th International Classification of Disease (ICD-10). In total, 58 countries or territories met the inclusion criteria.

### Methods of suicide

Following the approach by Ajdacic-Gross *et al*,<sup>10</sup> we classified suicide into seven categories based on the ICD-10 codes: (1) poisoning by pesticides (X68); (2) all other poisoning (X60–X67, X69); (3) firearms and explosives (X72–X75), (4) hanging (X70); (5) jumping from height (X80); (6) drowning (X71); (7) other methods (X76–79, X81–84).

### Data analysis

We performed interpolation and (or) extrapolation to impute the missing values from 2000 to 2015 for each country.<sup>17</sup> Specifically, the mean death rate of the first or last 3 years was extrapolated to impute the missing values in the starting or ending years. For missing values occurring in the middle of the time series, we replaced them with the mean death rate of all available data in a 7-year window (3 years on either side around the year with missing values).<sup>17</sup> The following missing values were estimated using these strategies: Australia, 2005; Austria, 2000, 2001; Bulgaria, 2000–2004, 2015; Canada, 2014, 2015; Costa Rica, 2000, 2015; Cuba, 2000; France, 2015; Guatemala, 2000–2004, 2015; Guyana, 2000, 2014, 2015; Hong Kong Special Administrative Region (Hong Kong SAR), 2000; Ireland, 2000–2006, 2015; Italy, 2000–2002; Mauritius, 2000–2004, 2015; New Zealand, 2014, 2015; Panama, 2015; Philippines, 2004, 2005, 2012–2015; Portugal, 2000, 2001, 2004–2006, 2015; Slovakia, 2011, 2015; Suriname, 2015; TFYR Macedonia, 2000–2005, 2014, 2015; Trinidad and Tobago, 2012–2015; UK, 2000; Uruguay, 2011; Uzbekistan, 2000–2003, 2006–2008, 2015 and Venezuela, 2014, 2015. In addition, we used a previously published method<sup>18</sup> to redistribute injury deaths coded as undetermined intent (ICD-10 codes: Y10–Y34).

We analysed data for persons aged  $\geq 15$  years because suicide is uncommon in children and early adolescence and determining suicidal intent in younger children can be difficult.<sup>19</sup> According to previous studies,<sup>20–21</sup> age was divided into four groups: 15–24 years, 25–44 years, 45–64 years and 65 years and older. Following preliminary analyses, we decided to combine adolescents and young adults into one age group (15–44 years) because they showed very similar suicide method patterns and changing trends in most countries. We calculated age-adjusted mortality rates using the direct standardisation method, in which the new WHO world standard population (WHO millennium)<sup>22</sup> was used as the reference population. A univariate negative binomial

regression model was run to examine the significance of changes in mortality between 2000 and 2015, using percentage change in mortality rate and its 95% CI. The percentage change was calculated as  $(\text{mortality rate ratio} - 1) \times 100$ , while the mortality rate ratio was calculated by dividing the mortality rate for 2015 with the corresponding rate of 2000.<sup>23</sup>

We first analysed the changing patterns of suicide for both sex. Then, method-specific subgroup analyses by sex and age group were conducted. Statistical analyses were completed using Stata V.12.1 (StataCorp).

## RESULTS

### Suicide among people aged 15–44 years old

Between 2000 and 2015, the total number of suicide deaths in the 58 included countries among adults aged 15–44 years decreased from 80 647 to 61 180. The male to female suicide mortality ratio ranged from 2.0 in Republic of Korea to 12.3 in Puerto Rico in 2000, and from 1.7 in Uzbekistan to 8.5 in Latvia in 2015.

For males, suicide mortality decreased in 37 countries but increased in 8 countries between 2000 and 2015, with the largest decrease in South Africa (–69%, 95% CI –73% to –65%) and the greatest increase in Ecuador (50%, 95% CI 31% to 73%) (table 1). Suicide mortality ranged greatly across the 58 countries in 2000 (from 4.8 to 85.9 per 100 000 people in Philippines and in Lithuania, respectively) and in 2015 (from 2.2 to 73.4 per 100 000 people in South Africa and in Guyana, respectively) (table 1). Between 2000 and 2015, the leading suicide method changed from other poisoning to hanging in Finland, from firearms and explosives to hanging in Columbia and South Africa, from pesticide poisoning to hanging in Trinidad and Tobago, and from hanging to pesticide poisoning in Suriname between 2000 and 2015 (figure 1, online supplementary tables S1 and S2). The most common suicide method was hanging in 54 of the 58 countries in 2015. Pesticide poisoning was most common in two countries, and firearms and explosives and jumping from a height in one country each (figure 1, online supplementary table S2).

For females, suicide mortality experienced a decrease in 19 countries (greatest in South Africa: –65%, 95% CI –73% to –55%) but an increase in eight countries (greatest in Mexico: 98%, 95% CI 76% to 122%) between 2000 and 2015 (table 1). Female suicide mortality rates also varied substantially across the 58 countries, with a 12-fold gap in 2000 (20.0 per 100 000 people in Guyana and 1.6 per 100 000 people in Mexico) and a 40-fold gap in 2015 (24.4 per 100 000 people in Guyana and 0.6 per 100 000 people in South Africa) (table 1). Between 2000 and 2015, the leading suicide method transferred from other poisoning to hanging in seven countries (New Zealand, France, Sweden, Puerto Rico, UK, Colombia, TFYR Macedonia), and from hanging to other poisoning in Germany and Mauritius (figure 1, online supplementary tables S1 and S2). In 2015, hanging, other poisoning, pesticide poisoning and jumping from a height were the most prevalent suicide methods in 47, 5, 3 and 3 countries for females, respectively (figure 1, online supplementary table S2).

### Suicide among people aged 45–64 years old

Among adults aged 45–64 years, the total number of suicide deaths across the 58 countries rose from 57 497 in 2000 to 67 777 in 2015. The male to female suicide mortality ratio ranged from 1.6 in Netherlands to 10.1 in Puerto Rico in 2000, and from 2.0 in Hong Kong SAR to 9.4 in Guatemala in 2015.

**Table 1** Age-standardised mortality (/100 000 persons) and per cent change in mortality between 2000 and 2015 among persons aged 15–44 years

Location	Male			Female		
	2000	2015	% change (95% CI)	2000	2015	% change (95% CI)

Hong Kong SAR	21.1	16.5	–21 (–33 to –6)	10.2	7.8	–18 (–34 to 3)
Romania	20.4	16.3	–15 (–23 to –6)	3.1	2.0	–31 (–47 to –9)
USA	19.9	23.4	17 (14 to 20)	4.6	7.0	44 (38 to 51)
Denmark	19.4	10.4	–47 (–57 to –34)	5.4	4.2	–22 (–46 to 15)
Sweden	18.4	17.1	–7 (–20 to 8)	7.6	8.4	7 (–15 to 35)
Republic of Korea	18.3	25.1	41 (33 to 48)	9.0	13.8	58 (47 to 71)
Puerto Rico	18.1	9.4	–47 (–60 to –30)	1.5	1.5	4 (–54 to 136)
Mauritius	18.1	18.2	1 (–31 to 47)	6.1	8.0	28 (–31 to 139)
Germany	17.8	13.4	–26 (–30 to –22)	4.6	4.4	–8 (–17 to 2)
UK	17.4	14.3	–18 (–23 to –13)	4.5	4.1	–9 (–19 to 2)
Cuba	17.1	12.6	–25 (–35 to –14)	6.8	2.9	–58 (–68 to –44)
Costa Rica	16.7	13.5	–18 (–34 to 2)	2.5	2.4	–2 (–44 to 72)
Argentina	16.0	18.2	13 (5 to 21)	3.8	4.5	19 (3 to 37)
Venezuela	15.8	7.1	–55 (–59 to –50)	2.6	1.3	–50 (–61 to –35)
Israel	15.0	7.7	–49 (–59 to –36)	2.8	1.8	–35 (–60 to 4)
Colombia	13.8	10.2	–26 (–32 to –20)	4.3	3.1	–30 (–39 to –20)
Uzbekistan	13.4	12.4	–6 (–14 to 4)	4.7	7.2	54 (34 to 78)
Portugal	12.8	11.2	–5 (–20 to 12)	3.1	2.5	–12 (–38 to 24)
Netherlands	12.7	13.2	1 (–11 to 15)	4.9	5.7	7 (–13 to 32)
Panama	11.7	7.0	–39 (–56 to –15)	2.1	1.8	–20 (–60 to 61)
Bulgaria	11.5	12.0	6 (–13 to 30)	3.3	3.0	–10 (–40 to 36)
Spain	10.7	8.2	–18 (–25 to –10)	2.7	2.8	13 (–5 to 34)
Guatemala	10.5	7.0	–30 (–41 to –17)	3.3	2.8	–19 (–38 to 6)
Ecuador	10.1	15.5	50 (31 to 73)	5.0	5.3	3 (–16 to 27)
Mexico	9.0	11.9	31 (25 to 39)	1.6	3.2	98 (76 to 122)
Brazil	8.7	10.5	25 (20 to 30)	2.2	2.9	29 (19 to 40)

Continued

Table 1 Continued

Location	Male			Female		
	2000	2015	% change (95% CI)	2000	2015	% change (95% CI)
Italy	8.5	7.6	−10 (−18 to −2)	2.3	1.9	−15 (−29 to 1)
TFYR Macedonia	8.2	8.9	13 (−27 to 74)	2.5	2.9	11 (−49 to 144)
South Africa	7.3	2.2	−69 (−73 to −65)	1.8	0.6	−65 (−73 to −55)
Philippines	4.8	5.7	19 (10 to 30)	1.8	1.9	9 (−5 to 25)

Mortality rates were age adjusted using the new WHO world standard population (WHO millennium).

For males, suicide mortality decreased in 27 countries (greatest decrease in South Africa: −76%, 95% CI −82% to −68%) but rose in 9 countries (greatest increase in Republic of Korea: 57%, 95% CI 48% to 66%) between 2000 and 2015 (table 2). A 30-fold and 55-fold mortality gap, respectively, occurred in 2000 (5.3 per 100 000 people in Philippines and 162.3 per 100 000 people in Lithuania) and in 2015 (1.6 per 100 000 people in South Africa and 88.1 per 100 000 people in Lithuania) (table 2). Hanging was the leading suicide method in 46 of the 58 countries in 2000 and in 53 of the 58 in 2015. Between 2000 and 2015, the most prevalent suicide method changed from other poisoning to hanging in New Zealand and Australia, from firearms and explosives to hanging in Switzerland and Columbia, from pesticide poisoning to hanging in Costa Rica, from other methods to hanging in Guatemala, and from pesticide poisoning to other poisoning in Trinidad and Tobago (figure 2, online supplementary tables S3 and S4). The most prevalent suicide method was hanging in 53 countries, pesticide poisoning in 2 countries, and other poisoning, firearms and explosives and jumping from a height in 1 country each in 2015 (figure 2, online supplementary table S4).

For females, suicide mortality decreased in 18 countries (largest in Kyrgyzstan: −61%, 95% CI −79% to −28%) but increased in 6 countries (greatest in Australia: 69%, 95% CI 36% to 110%) between 2000 and 2015 (table 2). Female suicide mortality ranged dramatically across the 58 countries both in 2000 (0.8 per 100 000 people for South Africa to 28.5 per 100 000 people for Lithuania) and in 2015 (0.5 per 100 000 people for South Africa to 18.0 per 100 000 people for Belgium) (table 2). Between 2000 and 2015, the most prevalent suicide method changed from

other poisoning to hanging in France, Colombia and UK; from firearms and explosives to hanging in Uruguay; from jumping from a height to hanging in Israel and Italy; from pesticide poisoning to hanging in Republic of Korea and Panama; from hanging to other poisoning in Hungary, Austria and Germany; and from pesticide poisoning to other poisoning in Trinidad and Tobago (figure 2, online supplementary tables S3 and S4). In 2015, the most prevalent suicide method was hanging in 40 countries, other poisoning in 14 countries, pesticide poisoning in 2 countries and jumping from a height in 1 country (figure 2, online supplementary table S4).

### Suicide among people aged 65 years and above

Among people aged 65 years and above, the total number of suicide deaths across the 58 countries increased from 37 170 in 2000 to 44 019 in 2015. The male to female suicide mortality ratio ranged from 1.5 per 100 000 people in Suriname to 17.3 per 100 000 people in Colombia in 2000, and from 1.9 per 100 000 people in Hong Kong SAR to 32.2 per 100 000 people in Puerto Rico in 2015.

For males, suicide mortality demonstrated statistically significant declines in 25 countries (largest decrease in Kyrgyzstan: −69%, 95% CI −82% to −44%) but increases in Ecuador and Republic of Korea (largest increase in Ecuador: 226%, 95% CI 97% to 438%) between 2000 and 2015 (table 3). A 24-fold and 37-fold suicide mortality rate gap, respectively, existed across the 58 countries in 2000 (5.3 per 100 000 people in South Africa and 132.4 per 100 000 people in Serbia) and in 2015 (2.8 per 100 000 people in South Africa and 106.0 per 100 000 people

Figure 1 Variation of method-specific suicide mortality rates among persons aged 15–44 years in 2000 and 2015 (/100 000 people) notes: mortality rates were age adjusted using the new WHO world standard population (who millennium).

**Table 2** Age-standardised mortality (/100 000 persons) and percent change in mortality between 2000 and 2015 among persons aged 45–64 years

Location	Male			Female		
	2000	2015	% change (95% CI)	2000	2015	% change (95% CI)

Mortality rates were age adjusted using the new WHO world standard population (WHO millennium).

in Republic of Korea) (table 3). Between 2000 and 2015, the most prevalent suicide method changed from firearms and explosives to hanging in five countries (Uruguay, Argentina, Canada, Colombia and Suriname) and from hanging to firearms and explosives in Finland (figure 3, online supplementary tables S5 and S6). The most common suicide method was hanging in 50 countries; firearms and explosives in 5 countries; and other poisoning, pesticide poisoning and jumping from a height in 1 country each in 2015 (figure 3, online supplementary table S6).

For females, suicide mortality decreased at a statistically significant rate in 26 countries (largest in Kyrgyzstan: −74%, 95% CI −90% to −32%) and increased in Republic of Korea and USA (greatest in Republic of Korea: 46%, 95% CI 32%, 61%) between 2000 and 2015 (table 3). Female suicide mortality ranged greatly across the 58 countries in both 2000 (0.8 per 100 000 people in South Africa and 48.2 per 100 000 people in Serbia) and in 2015 (0.3 per 100 000 people in South Africa and 32.2 per 100 000 people in Republic of Korea (table 3). Between 2000 and 2015, the most prevalent suicide method changed from other poisoning to hanging in Costa Rica; from pesticide poisoning to hanging in Republic of Korea and Ecuador; from pesticide poisoning to other poisoning in Trinidad and Tobago; from hanging to other poisoning in Finland, Norway and Netherlands; and from firearms and explosives to other poisoning in the USA (figure 3, online supplementary tables S5 and S6). In 2015, the most frequent suicide method was hanging in 42 countries, other poisoning in 13 countries, pesticide poisoning in 2 countries, and jumping from a height in 1 country (figure 3, online supplementary table S6).

## DISCUSSION

### Key findings

Using the WHO mortality database, this study updates previously published research<sup>10</sup> with more recent sex-specific, age-specific and country-specific suicide rates, as well as reporting new patterns of suicide mortality between 2000 and 2015 in 58 countries with robust subgroup rates. Suicide mortality declined substantially for both sexes and all included age groups in most but not all of the 58 countries between 2000 and 2015. Males consistently had much higher suicide mortality rates than females in all countries. Hanging replaced non-pesticide poisoning as the most common suicide method in the majority of 58 countries between 2000 and 2015. Sex-specific suicide mortality methods varied across the 58 countries for all three age groups. The spectrum of suicide methods generally remained stable in most countries but changed notably in a few countries between 2000 and 2015.

### Interpretation of findings

The decrease in suicide mortality in most countries may reflect the effects of global and national prevention efforts.<sup>2</sup> In the past few decades, WHO has published several documents to advocate global action to prevent suicide. These include efforts to inspire governments and policy-makers to establish or revise national suicide prevention strategies<sup>24</sup> and to advocate for effective evidence-based interventions such as promoting responsible media reporting<sup>25</sup> and improving risk intervention through crisis helplines. A few nations, such as Switzerland and Australia, now

Mortality rates were age adjusted using the new WHO world standard population (WHO millennium).

include restriction of suicide means in their national suicide prevention strategies and programmes.<sup>9 26</sup> In addition, improved availability of mental health and welfare services may have contributed to global reductions in suicide mortality.<sup>27 28</sup>

During the study period, a number of countries witnessed significant changes in the suicide method used.<sup>14 15 29</sup> These changes are likely due to trends in sociocultural acceptability of suicide and mental health, plus access to specific suicide methods.<sup>6 30</sup> The rising rate of suicide by hanging in many countries, for example, might be attributed to prevention efforts focused on limiting access to firearms.<sup>14</sup> In addition, unlike suicide by other methods, suicide by hanging is less likely to be misclassified as unintentional or undetermined death.<sup>31</sup> The decrease of suicide by other poisoning (typically drug poisoning) in some countries has been linked to the implementation of careful and appropriate medication prescribing and dosing, such as restricting size of analgesic packs in the UK<sup>32</sup> and withdrawal of co-proxamol throughout Europe.<sup>33</sup> Improved firearm legislation and restriction of firearm availability may partially explain the drops in suicide mortality by firearm in New Zealand,<sup>34</sup> Australia<sup>35</sup> and in Switzerland.<sup>36</sup> Finally, the adoption of strengthened pesticide regulations and restrictions may have led to substantial decreases in suicide by pesticide in Republic of Korea, despite an increase in overall suicide mortality in this nation.<sup>37</sup>

Notably, some countries witnessed significant increases in suicide mortality between 2000 and 2015 (eg, the Republic of Korea and the USA). Published studies suggest the increases may be explained by various factors, including economic recession,<sup>38 39</sup> widening income inequalities,<sup>40</sup> increased unemployment<sup>41</sup> and ease access to highly lethal methods like firearms.

Birth cohort effects may also contribute, given cohort population exposures to the Great Depression and the Korean War.<sup>42</sup>

In accordance with previous reports,<sup>43</sup> this study reported comparatively higher suicide mortality in males compared with females in all 58 included countries. Male–female disparities are interpreted as sex differences in help-seeking behaviour to treat mental health crises and suicidality,<sup>44</sup> ownership of guns,<sup>45</sup> unemployment rates,<sup>46</sup> life roles and alcohol consumption and dependence.<sup>44</sup> Males also are more likely to choose highly lethal suicide methods compared with females.<sup>47</sup>

Also in concordance with previous reports,<sup>2 10</sup> we found significant variation in suicide rates across countries. These variations can be interpreted as the combined effects of socioeconomic development, religion, laws and policies, availability of lethal methods, suicide prevention efforts, mental health treatment availability and cultural acceptance of it, and prehospital and hospital treatment.<sup>4 46</sup>

## Policy implications

Our findings offer societal benefits through two major policy implications. First, the recent decrease of suicide mortality in most of the 58 included countries highlights the apparent success of global and national suicide prevention efforts. The progress demonstrates the role of evidence-based public health interventions and suggests that the SDGs target for suicide prevention may be achievable if the recommended interventions are fully implemented. Second, our results underscore the urgency and importance of efforts to reduce disparities in suicide mortality and mortality change. The global suicide prevention community,

**Figure 3** Variation of method-specific suicide mortality rates among persons aged 65 years and older in 2000 and 2015 (/100 000 people) notes: mortality rates were age-adjusted using the new who world standard population (who millennium).

and especially the governments of countries with high suicide mortality rates and those with small suicide mortality reductions (or mortality increases) between 2000 and 2015, should collaborate to identify reasons for the disparities and develop solutions to reduce them. The reduction of disparities between countries, and subsequent reduction of suicide rates in high-risk countries, will be a critical strategy to attain the global SDGs suicide prevention target. From a research perspective, continued work to generate evidence-based strategies for global and national suicide policy interventions should be pursued.

### Study limitations

Our analyses were limited by three factors. First, we were limited by data availability. Many countries were excluded because they did not report data to the WHO mortality database, including China, India and Russia. We also excluded countries with small annual suicide deaths in order to obtain robust subgroup suicide mortality rates by sex, age group and suicide method. Complete analyses could be made if the GBD study group extended their database to offer detailed groups of fatalities by suicide method rather than estimating only two groups (self-harm by firearm and self-harm by other specified means).<sup>1</sup> Second, due to lack of data concerning relevant risk factors such as previous suicide attempts, mental health disorders, substance use disorders and inappropriate media reporting, we cannot explain the causality of suicide rate changes and mortality differences by sex, age, suicide method and country. Last, given the social taboo of suicide in almost all cultures, data on suicide rates suffer from challenges in data quality, including underreporting and misclassification. Such effects likely impact our results, especially for those countries with poor-quality suicide mortality data and those with particularly strong sociocultural biases concerning suicidality.

### CONCLUSIONS

Substantial suicide mortality decreases occurred between 2000 and 2015 in 37 of the 58 countries (64%) included in this study. The suicide spectrum by method experienced substantial changes in several countries, likely reflecting combined influences of changes in population sociodemographic characteristics and organised suicide prevention efforts. Results amplify calls for further research to explore specific drivers of the observed changes, including especially the increases in suicide rates we

witnessed in eight countries, and to understand disparities in suicide rates across countries. Results also amplify urgent need to continue global suicide prevention efforts.

### What is already known on this subject

- Suicide is a serious global public health problem.
- Suicide method varies substantially by sex and age group and across countries.
- Recent suicide mortality by method has not been examined across countries.

### What this study adds

- Between 2000 and 2015, suicide mortality decreased in 37 of the included 58 countries but increased in 8 countries.
- The suicide spectrum by method experienced substantial changes in several countries between 2000 and 2015.
- Hanging is the most prevalent suicide method in most included countries.
